Fundamentals of Radiation Physics in Nuclear Medicine

Types of Radiation Used in Nuclear Medicine

Radioactive isotopes, or radionuclides, emit different forms of ionizing radiation that are harnessed for imaging and treatment purposes. The primary types include:

- **Gamma Rays:** High-energy photons emitted during radioactive decay, used extensively in diagnostic imaging such as SPECT (Single Photon Emission Computed Tomography).
- **Beta Particles:** Electrons or positrons emitted during decay, utilized in therapeutic applications like radioiodine therapy for thyroid cancer.
- **Alpha Particles:** Helium nuclei with high linear energy transfer, used in targeted alpha therapy but less common in routine nuclear medicine due to their limited tissue penetration.

Understanding these radiation types is essential for optimizing image quality, minimizing patient exposure, and designing effective treatment protocols.

Radioactive Decay and Half-Life

Radioactive decay is the process by which unstable isotopes transform into more stable forms, emitting radiation in the process. Key concepts include:

- **Half-Life:** The time required for half of the radioactive atoms in a sample to decay. Different isotopes have varying half-lives, influencing their suitability for specific medical applications.
