Problem 2: Calculating Bond Enthalpy Change in a Reaction

Question:

Calculate the enthalpy change (ΔH) for the reaction:

Given that:

Solution:

- Write the bond-breaking and bond-forming steps:

- Bonds broken: 1 H-H and 1 Cl-Cl
- Bonds formed: 2 H-Cl

- Calculate total energy for bonds broken:

$$\text{Energy to break} = D(\text{H-H}) + D(\text{Cl-Cl}) = 432 + 243 = 675 \text{ kJ}$$

- Calculate total energy for bonds formed:

\[

$$\text{Energy released} = 2 \times D(\text{H-Cl}) = 2 \times 431 = 862 \text{ kJ}$$

\]

- Calculate ΔH :

\[

$$\Delta H = \text{Bonds broken} - \text{Bonds formed} = 675 - 862 = -187 \text{ kJ}$$

Question What is the primary difference between ionic and covalent bonding in inorganic chemistry? Ionic bonding involves the transfer of electrons between atoms, resulting in positively and negatively charged ions held together by electrostatic forces, while covalent bonding involves sharing of electron pairs between atoms to achieve a stable electronic configuration. How do you determine the oxidation state of an element in an inorganic compound? To determine the oxidation state, assign known oxidation numbers based on the element's typical charges, consider the overall charge of the compound or ion, and use algebraic methods to solve for unknown oxidation states within the molecule. Solve for the empirical formula of a compound that contains 40% sulfur and 60% oxygen by mass. Assuming 100 g of the compound: sulfur = 40 g, oxygen = 60 g. Convert to moles: $S = 40/32.06 = 1.247 \text{ mol}$; $O = 60/16.00 = 3.75 \text{ mol}$. Divide by the smallest number: $S = 1.247/1.247 = 1$; $O = 3.75/1.247 = 3.01 \approx 3$. Empirical formula: SO_3 . Calculate the molar mass of potassium permanganate ($KMnO_4$). The molar mass is calculated as: $K (39.10) + Mn (54.94) + 4 \times O (4 \times 16.00) = 39.10 + 54.94 + 64.00 = 158.04 \text{ g/mol}$. Determine the coordination number and geometry of a complex ion $[Co(NH_3)_6]^{3+}$. The complex has six ligands (NH_3 molecules) attached to

the cobalt ion, giving a coordination number of 6. The geometry is octahedral. What is the principle behind the Born-Haber cycle in calculating lattice enthalpy? The Born-Haber cycle uses Hess's law to relate the lattice enthalpy of an ionic solid to ionization energies, electron affinities, sublimation energy, and the dissociation energy of molecules, allowing the calculation of lattice energy from experimentally known values. Solve for the concentration of a solution if 10 mL of 0.5 M H_2SO_4 is diluted to 250 mL. Using $C_1V_1 = C_2V_2$: $(0.5 \text{ M})(10 \text{ mL}) = C_2(250 \text{ mL})$. Hence, $C_2 = (0.5 \times 10) / 250 = 5 / 250 = 0.02 \text{ M}$. Explain the concept of ligand field theory in inorganic chemistry. Ligand field theory explains the bonding and properties of coordination compounds by considering the interaction between metal d-orbitals and ligand electron pairs, leading to splitting of d-orbitals and influencing magnetic and spectral properties. Calculate the pH of a 0.01 M HCl solution. Since HCl is a strong acid, it dissociates completely: $[\text{H}^+] = 0.01 \text{ M}$. Therefore, $\text{pH} = -\log[\text{H}^+] = -\log(0.01) = 2$. What is the purpose of a spectrochemical series in inorganic chemistry? The spectrochemical series ranks ligands based on their ability to split the d-orbital energies in a metal complex, affecting the color and electronic properties of the complex.
