Question What are the main functions of the skeletal system? The skeletal system provides structural support, protects internal organs, facilitates movement by anchoring muscles, stores minerals like calcium and phosphorus, and produces blood cells in the bone marrow. How many bones are typically found in the adult human skeleton? An adult human skeleton typically consists of 206 bones. What is the difference between compact and spongy bone? Compact bone is dense and provides strength and support, while spongy bone has a porous, lattice-like structure that reduces weight and contains bone marrow. Name three types of joints and give an example of each. The three types of joints are: fibrous joints (e.g., sutures in the skull), cartilaginous joints (e.g., intervertebral discs), and synovial joints (e.g., the knee joint). What role do osteocytes play in the skeletal system? Osteocytes are mature bone cells that maintain bone tissue, regulate mineral content, and communicate with other bone cells to facilitate repair and remodeling. Which bones are part of the axial skeleton? The axial skeleton includes the skull, vertebral column, and thoracic cage (rib cage). What is osteoporosis and how does it affect the skeletal system? Osteoporosis is a condition characterized by decreased bone density and increased fragility, making bones more susceptible to fractures.
